## Example 3.5 The MA(1) Process

Consider the following process, namely *moving average* of order 1:

$$x_t = w_t + \theta w_{t-1}, \quad \text{where } w_t \sim \text{wn}(0, \sigma_w^2).$$

Show that

(a)  $E(x_t) = 0$  for all  $t$

(b)

$$\gamma(h) = \begin{cases} (1 + \theta^2)\sigma_w^2 & \text{if } h = 0 \\ \theta\sigma_w^2 & \text{if } h = \pm 1 \\ 0 & \text{otherwise} \end{cases}$$

(c)

$$\rho(h) = \begin{cases} 1 & \text{if } h = 0 \\ \frac{\theta}{1+\theta^2} & \text{if } h = \pm 1 \\ 0 & \text{otherwise} \end{cases}$$

## Example 3.5 The Sample Path of an MA(1) Process

Consider the following process, namely *moving average* of order 1:

$$x_t = w_t + \theta w_{t-1}, \quad \text{where } w_t \sim \text{wn}(0, \sigma_w^2).$$

Let  $\theta = 0.9$ , i.e.  $\rho(1) = 0.497$  in this case.

Notice that:  $\rho(h) = \begin{cases} \frac{\theta}{1+\theta^2} & \text{if } h = \pm 1 \\ 0 & \text{if } |h| \geq 2 \end{cases}$

## Example 3.5 The Sample Path of an MA(1) Process

Consider the following process, namely *moving average* of order 1:

$$x_t = w_t + \theta w_{t-1}, \quad \text{where } w_t \sim \text{wn}(0, \sigma_w^2).$$

Let  $\theta = -0.9$ , i.e.  $\rho(1) = -0.497$  in this case.

Notice that:  $\rho(h) = \begin{cases} \frac{\theta}{1+\theta^2} & \text{if } h = \pm 1 \\ 0 & \text{if } |h| \geq 2 \end{cases}$

## Example 3.6 Non-uniqueness of MA Models and Invertibility

Consider the following MA(1) process:

$$x_t = w_t + \theta w_{t-1}, \quad \text{where } w_t \stackrel{\text{iid}}{\sim} \mathcal{N}(0, \sigma_w^2).$$

Then one can see non-uniqueness of the MA model in the following sense:

- 1 Autocorrelation function: Notice that for any  $a \neq 0$ ,  $\rho(h)$  of an MA(1) is same for  $\theta = a$  and  $\theta = \frac{1}{a}$ .
- 2 Autocovariance function: For any  $a \neq 0$  and  $c > 0$ ,  $\gamma(h)$  of an MA(1) is same for  $\theta = a, \sigma_w = c$  and  $\theta = \frac{1}{a}, \sigma_w = ac$ .

## Example 3.6 Non-uniqueness of MA Models and Invertibility

Therefore, given  $a \neq 0$ , the MA(1) processes

$$x_t = w_t + aw_{t-1}, \quad \text{where } w_t \stackrel{\text{iid}}{\sim} \mathcal{N}(0, \sigma_w^2),$$

and

$$x_t = w_t + \frac{1}{a}w_{t-1}, \quad \text{where } w_t \stackrel{\text{iid}}{\sim} \mathcal{N}(0, a^2\sigma_w^2),$$

represent the same time series model.

Which choice is preferable?

## Example 3.6 Non-uniqueness of MA Models and Invertibility

We notice that the following MA(1) process

$$x_t = w_t + \theta w_{t-1}, \quad \text{where } w_t \stackrel{\text{iid}}{\sim} \mathcal{N}(0, \sigma_w^2),$$

can be rewritten as follows:

$$w_t = -\theta w_{t-1} + x_t$$

and therefore

$$w_t = \sum_{j=0}^{\infty} (-\theta)^j x_{t-j}, \quad \text{if } |\theta| < 1.$$

If such infinite AR representation is possible (i.e.  $|\theta| < 1$  in the case of MA(1)), the process is called an *invertible* process

# Definition of Moving Average Model

Def.

Assume that

$$x_t = w_t + \theta_1 w_{t-1} + \theta_2 w_{t-2} + \dots + \theta_q w_{t-q},$$

where  $w_t \sim \mathcal{WN}(0, \sigma_w^2)$  and  $\theta_1, \theta_2, \dots, \theta_q$  are constants ( $\theta_q \neq 0$ ), then the process  $x_t$  is called *moving average model* of order  $q$ , abbreviated MA( $q$ ).

# Definition of Moving Average Model Model

Def.

The moving average operator is defined to be

$$\theta(B) = 1 + \theta_1 B + \theta_2 B^2 + \dots + \theta_q B^q.$$

Note:

Then the moving average model of order  $q$  can be written as follows:

$$x_t = \theta(B)w_t.$$

# Definition of Autoregressive Moving Average Model

Def.

Assume that

$$x_t = \alpha + \phi_1 x_{t-1} + \phi_2 x_{t-2} + \dots + \phi_p x_{t-p} \\ + w_t + \theta_1 w_{t-1} + \theta_2 w_{t-2} + \dots + \theta_q w_{t-q}$$

is a stationary process, where

$$w_t \sim \text{wn}(0, \sigma_w^2),$$

$\phi_1, \phi_2, \dots, \phi_p$  are constants ( $\phi_p \neq 0$ ),

$\theta_1, \theta_2, \dots, \theta_q$  are constants ( $\theta_q \neq 0$ ), and

there is no parameter redundancy,

then the process  $x_t$  is called *autoregressive moving average model* of order  $p, q$ , abbreviated  $\text{ARMA}(p, q)$ .

# Definition Autoregressive Moving Average Model

Note:

Assuming  $\alpha = 0$ , the autoregressive moving average model of order  $p, q$  can be written as follows:

$$\phi(B)x_t = \theta(B)w_t,$$

where

$$\phi(B) = 1 - \phi_1 B - \phi_2 B^2 - \dots - \phi_p B^p$$

and

$$\theta(B) = 1 + \theta_1 B + \theta_2 B^2 + \dots + \theta_q B^q.$$

# Parameter Redundancy

Remark:

We notice that if both sides of

$$\phi(B)x_t = \theta(B)w_t$$

are left-multiplied by some operator  $\eta(B)$ , we get an equivalent model:

$$\eta(B)\phi(B)x_t = \eta(B)\theta(B)w_t$$

with possibly more parameters.

## Example 3.7 Parameter Redundancy

Let

$$x_t = w_t.$$

This process, however, is equivalent to

$$\underbrace{(1 - 0.5B)}_{\eta(B)} x_t = \underbrace{(1 - 0.5B)}_{\eta(B)} w_t,$$

i.e. the following seemingly ARMA(1,1):

$$x_t = 0.5x_{t-1} - 0.5w_{t-1} + w_t.$$

For example, if we fit ARMA(1,1) to a realization of  $x_t = w_t$ , we can get significant results for all parameters - over-parametrized model.

# Requirements on AR and MA polynomials

We will require that the AR and MA polynomials of  $\text{ARMA}(p, q)$ ,

$$\phi(z) = 1 - \phi_1 z - \dots - \phi_p z^p, \phi_p \neq 0,$$

and

$$\theta(z) = 1 + \theta_1 z + \dots + \theta_q z^q, \theta_q \neq 0,$$

have no common factors.

# Definition of Causality

Def.

ARMA( $p, q$ ) model is called *causal* if it can be written as:

$$\begin{aligned}x_t &= \sum_{j=0}^{\infty} \psi_j w_{t-j} \\ &= \psi_0 w_t + \psi_1 w_{t-1} + \psi_2 w_{t-2} + \dots,\end{aligned}$$

where  $\sum_{j=0}^{\infty} |\psi_j| < \infty$ .

# Definition of Causality

Note

Let

$$\begin{aligned}\psi(B) &= \sum_{j=0}^{\infty} \psi_j B^j \\ &= \psi_0 + \psi_1 B + \psi_2 B^2 + \dots,\end{aligned}$$

then a causal  $x_t$  can be written as follows (“MA representation”):

$$x_t = \psi(B)w_t.$$

# Definition of Invertibility

Def.

ARMA( $p, q$ ) model is called *invertible* if it can be written as:

$$\begin{aligned}w_t &= \sum_{j=0}^{\infty} \pi_j x_{t-j} \\ &= \pi_0 x_t + \pi_1 x_{t-1} + \pi_2 x_{t-2} + \dots,\end{aligned}$$

where  $\sum_{j=0}^{\infty} |\pi_j| < \infty$ .

# Definition of Invertibility

Note

Let

$$\begin{aligned}\pi(B) &= \sum_{j=0}^{\infty} \pi_j B^j \\ &= \pi_0 + \pi_1 B + \pi_2 B^2 + \dots,\end{aligned}$$

then an invertible  $x_t$  can be written as follows (“AR representation”):

$$\pi(B)x_t = w_t.$$
