4 Behavior of the ACF and PACF for ARMA Models

Example: Causality of an MA(q) Process

Let x_t be MA(q):

$$x_t = w_t + \theta_1 w_{t-1} + \theta_2 w_{t-2} + \dots + \theta_q w_{t-q}, \quad \text{where } w_t \sim \text{wn}(0, \sigma_w^2),$$

which can be written as:

$$\underbrace{1}_{\phi(B)} x_t = (1 + \theta_1 B + \theta_2 B^2 + \dots + \theta_q B^q) w_t,$$

The causality condition for an MA(q) then is

$$\underbrace{1}_{\phi(z)} \neq 0 \quad \text{for all } |z| \leq 1,$$

i.e. MA(q) is always causal!

4 Behavior of the ACF and PACF for ARMA Models

Example: Causality of an AR(1) Process

Let x_t be AR(1):

$$x_t = \phi x_{t-1} + w_t, \quad \text{where } w_t \sim \text{wn}(0, \sigma_w^2),$$

which can be equivalently rewritten as:

$$\underbrace{(1 - \phi B)}_{\phi(B)} x_t = w_t.$$

The causality condition for an AR(1) then is

$$\underbrace{1 - \phi z}_{\phi(z)} \neq 0 \quad \text{for all } |z| \leq 1,$$

or

$$\left| \frac{1}{\phi} \right| > 1.$$

4 Behavior of the ACF and PACF for ARMA Models

Example 3.8 Parameter Redundancy, Causality, Invertibility

Let

$$x_t = 0.4x_{t-1} + 0.45x_{t-2} + w_t + w_{t-1} + 0.25w_{t-2},$$

which is equivalent to

$$\underbrace{(1 - 0.4B - 0.45B^2)}_{=\phi(B)} x_t = \underbrace{(1 + B + 0.25B^2)}_{=\theta(B)} w_t.$$

Is this process ARMA(2,2)?

We notice that

$$\underbrace{(1 + 0.5B)(1 - 0.9B)}_{=\phi(B)} x_t = \underbrace{(1 + 0.5B)(1 + 0.5B)}_{=\theta(B)} w_t,$$

i.e. the ARMA(1,1) model!

Example 3.8 Parameter Redundancy, Causality, Invertibility

We have the following ARMA(1,1) process:

$$\underbrace{(1 - 0.9B)}_{=\phi(B)} x_t = \underbrace{(1 + 0.5B)}_{=\theta(B)} w_t,$$

Root of $\phi(z) = 0$ is $z = \frac{10}{9}$, which is outside of unit circle: $|z| > 1$.
Therefore, this process is causal.

To get the coefficients ψ_j , $j = 0, 1, 2, \dots$, we can write $\psi(z) = \frac{\theta(z)}{\phi(z)}$, or

$$\underbrace{(1 - 0.9z)}_{\phi(z)} \underbrace{(\psi_0 + \psi_1 z + \psi_2 z^2 + \dots)}_{\psi(z)} = \underbrace{1 + 0.5z}_{\theta(z)},$$

which is equivalent to

$$\psi_0 + (\psi_1 - 0.9\psi_0)z + (\psi_2 - 0.9\psi_1)z^2 + \dots = 1 + 0.5z.$$

$$\Rightarrow x_t = w_t + 1.4 \sum_{j=1}^{\infty} 0.9^{j-1} w_{t-j} \text{ ("MA representation").}$$

Example 3.8 Parameter Redundancy, Causality, Invertibility

We have the following ARMA(1,1) process:

$$\underbrace{(1 - 0.9B)}_{=\phi(B)} x_t = \underbrace{(1 + 0.5B)}_{=\theta(B)} w_t,$$

Root of $\theta(z) = 0$ is $z = -2$, which is outside of unit circle: $|z| > 1$.
Therefore, this process is invertible.

To get the coefficients π_j , $j = 0, 1, 2, \dots$, we can write $\pi(z) = \frac{\phi(z)}{\theta(z)}$, or

$$\underbrace{(1 + 0.5z)}_{\theta(z)} \underbrace{(\pi_0 + \pi_1 z + \pi_2 z^2 + \dots)}_{\pi(z)} = \underbrace{1 - 0.9z}_{\phi(z)},$$

which is equivalent to

$$\pi_0 + (\pi_1 + 0.5\pi_0)z + (\pi_2 + 0.5\pi_1)z^2 + \dots = 1 - 0.9z.$$

$$\Rightarrow w_t = -1.4 \sum_{j=0}^{\infty} (-0.5)^{j-1} x_{t-j} \text{ ("AR representation")}. \quad \leftarrow \square \rightarrow \leftarrow \square \rightarrow \leftarrow \square \rightarrow \leftarrow \square \rightarrow \leftarrow \square \rightarrow$$

Example 3.8 Parameter Redundancy, Causality, Invertibility

We have the following ARMA(1,1) process:

$$\underbrace{(1 - 0.9B)}_{=\phi(B)} x_t = \underbrace{(1 + 0.5B)}_{=\theta(B)} w_t,$$

which is

$$x_t = 0.9x_{t-1} + 0.5w_{t-1} + w_t,$$

and obtained

$$w_t = -1.4 \sum_{j=0}^{\infty} (-0.5)^{j-1} x_{t-j},$$

then

$$x_t = 1.4 \sum_{j=1}^{\infty} (-0.5)^{j-1} x_{t-j} + w_t.$$

Example 3.9 Causal Conditions for an AR(2) Process

Let x_t be AR(2):

$$x_t = \phi_1 x_{t-1} + \phi_2 x_{t-2} + w_t, \quad \text{where } w_t \sim \text{wn}(0, \sigma_w^2),$$

which can be equivalently rewritten as:

$$\underbrace{(1 - \phi_1 B - \phi_2 B^2)}_{\phi(B)} x_t = w_t.$$

The causality condition then is

$$\underbrace{1 - \phi_1 z - \phi_2 z^2}_{\phi(z)} \neq 0 \quad \text{for all } |z| \leq 1,$$

or

$$\left| \frac{-\phi_1 \pm \sqrt{\phi_1^2 + 4\phi_2}}{2\phi_2} \right| > 1.$$

Example 3.9 Causal Conditions for an AR(2) Process

We notice that the causality condition $\left| \frac{-\phi_1 \pm \sqrt{\phi_1^2 + 4\phi_2}}{2\phi_2} \right| > 1$ is equivalent to

$$\phi_1 + \phi_2 < 1, \phi_2 - \phi_1 < 1, \text{ and } |\phi_2| < 1.$$

4 Behavior of the ACF and PACF for ARMA Models

Definition of Partial Autocorrelation Function (PACF)

Assume x_t is stationary. Let's denote regression of

x_{t+h} on $\{x_{t+h-1}, x_{t+h-2}, \dots, x_{t+1}\}$ by \hat{x}_{t+h} :

$$\begin{aligned}\hat{x}_{t+h} &= \sum_{j=1}^{h-1} \beta_j x_{t+h-j} \\ &= \beta_1 x_{t+h-1} + \beta_2 x_{t+h-2} + \dots + \beta_{h-1} x_{t+1},\end{aligned}$$

where coefficients β_j , $j = 1, 2, \dots, h-1$, minimize

$$\mathbb{E} \left[(x_{t+h} - \hat{x}_{t+h})^2 \right].$$

Definition of Partial Autocorrelation Function (PACF)

Similarly, let's denote regression of

x_t on $\{x_{t+1}, x_{t+2}, \dots, x_{t+h-1}\}$ by \hat{x}_t :

$$\begin{aligned}\hat{x}_t &= \sum_{j=1}^{h-1} \beta_j x_{t+j} \\ &= \beta_1 x_{t+1} + \beta_2 x_{t+2} + \dots + \beta_{h-1} x_{t+h-1},\end{aligned}$$

where coefficients β_j , $j = 1, 2, \dots, h-1$, minimize

$$\mathbb{E} \left[(x_t - \hat{x}_t)^2 \right].$$

Definition of Partial Autocorrelation Function (PACF)

Remark

Because x_t is stationary, the set of coefficients β_j in

$$\begin{aligned}\hat{x}_{t+h} &= \sum_{j=1}^{h-1} \beta_j x_{t+h-j} \\ &= \beta_1 x_{t+h-1} + \beta_2 x_{t+h-2} + \dots + \beta_{h-1} x_{t+1},\end{aligned}$$

is, in fact, same as in

$$\begin{aligned}\hat{x}_t &= \sum_{j=1}^{h-1} \beta_j x_{t+j} \\ &= \beta_1 x_{t+1} + \beta_2 x_{t+2} + \dots + \beta_{h-1} x_{t+h-1},\end{aligned}$$

Definition of Partial Autocorrelation Function (PACF)

Def.

Let x_t be a stationary process, then ϕ_{hh} ($h = 0, 1, 2, \dots$), defined as:

$$\phi_{00} = \text{Corr}(x_t, x_t) = \rho(0) = 1,$$

$$\phi_{11} = \text{Corr}(x_{t+1}, x_t) = \rho(1),$$

$$\phi_{hh} = \text{Corr}(x_{t+h} - \hat{x}_{t+h}, x_t - \hat{x}_t), h \geq 2,$$

is called *partial autocorrelation function* (PACF).

Here, \hat{x}_{t+h} and \hat{x}_t are as defined above:

$$\hat{x}_{t+h} = \sum_{j=1}^{h-1} \beta_j x_{t+h-j} = \beta_1 x_{t+h-1} + \beta_2 x_{t+h-2} + \dots + \beta_{h-1} x_{t+1},$$

$$\hat{x}_t = \sum_{j=1}^{h-1} \beta_j x_{t+j} = \beta_1 x_{t+1} + \beta_2 x_{t+2} + \dots + \beta_{h-1} x_{t+h-1}.$$

Example 3.15 The PACF of an AR(1)

Let x_t be AR(1):

$$x_t = \phi x_{t-1} + w_t, \quad \text{where } w_t \sim \text{wn}(0, \sigma_w^2),$$

where $|\phi| < 1$ (i.e. x_t is causal) then

$$\phi_{00} = 1,$$

$$\phi_{11} = \rho(1) = \phi,$$

$$\begin{aligned} \phi_{22} &= \text{Corr}(x_{t+2} - \hat{x}_{t+2}, x_t - \hat{x}_t) \\ &= \text{Corr}(\underbrace{x_{t+2} - \phi x_{t+1}}_{w_{t+2}}, \underbrace{x_t - \phi x_{t+1}}_{\text{depends on past}}) = 0 \end{aligned}$$

For causal AR(1),

$$\phi_{hh} = 0 \quad \text{for all } h > 1,$$

Example 3.16 The PACF of an AR(p)

Let x_t be AR(p),

$$x_t = \phi_1 x_{t-1} + \phi_2 x_{t-2} + \dots + \phi_p x_{t-p} + w_t, \quad \text{where } w_t \sim \text{wn}(0, \sigma_w^2),$$

be causal then

$$\phi_{hh} = 0 \quad \text{for all } h > p,$$

because $\hat{x}_{t+1} = \phi_1 x_{t-1} + \phi_2 x_{t-2} + \dots + \phi_p x_{t-p}$ for $h > p$.

Example 3.17 The PACF of an Invertible MA(q)

Let x_t be MA(q),

$$x_t = w_t + \theta_1 w_{t-1} + \theta_2 w_{t-2} + \dots + \theta_q w_{t-q} + w_t, \quad \text{where } w_t \sim \text{wn}(0, \sigma_w^2),$$

be invertible then

$$x_t = - \sum_{j=1}^{\infty} \pi_j x_{t-j} + w_t$$

and PACF will never cut off.

Behavior of the ACF and PACF for ARMA Models

	$AR(p)$	$MA(q)$	$ARMA(p, q)$
ACF	Tails off	Cuts off after lag q	Tails off
PACF	Cuts off after lag p	Tails off	Tails off
